**BLAST**

**Basic Local Alignment Search Tool**

BLAST finds regions of similarity between biological sequences. The program compares nucleotide or protein sequences to sequence databases and calculates the statistical significance.

**Web BLAST**

Nucleotide BLAST: nucleotide > nucleotide

Protein BLAST: protein > protein

tblastn: protein > translated nucleotide

blastx: translated nucleotide > protein

**NCBI Virus**

**BLAST**

**BLAST Assembled RefSeq Genomes**

Choose a species genome to search, or list all genomes in BLAST databases.

- Human
- Mouse
- Arabidopsis thaliana
- Oryza sativa
- Bos taurus
- Danio rerio
- Drosophila melanogaster
- Gallus gallus
- Fox troglodytes
- Aplysia

**Basic BLAST**

Choose a BLAST program to run:

- nucleotide\_blast: Search a nucleotide database using a nucleotide query
- protein\_blast: Search a protein database using a protein query
- tblastx: Search protein database using a translated nucleotide query
- tblastn: Search translated nucleotide database using a protein query
- tblastx: Search translated nucleotide database using a translated nucleotide query

**Specialized BLAST**

Choose a type of specialized search (or database name in parentheses):

- Make specific primers with Primer-BLAST
- Search gaps in a sequence
- Find conserved domains in your sequence (cd-hit)
- Search sequences that have specific annotations (blast2go)
- Search immunoglobulin and T cell receptor sequences (tblastx)
- Search sequence for specific conserved domains (tblastx)
- Allison two (or more) sequences using BLAST (tblastx)
- Search protein or nucleotide targets in PubChem BioAssay
- Search SRA by expression

Created: June 23, 2008; Last Update: March 24, 2022. Estimated reading time: 2 minutes. As part of our effort to improve BLAST+, we have implemented usage reporting to collect limited data. This information shows us whether BLAST+ is being used by the community, and therefore is worth being maintained and developed by NCBI. It also allows us to focus our development efforts on the most used aspects of BLAST+. If possible, please report your usage, so we can continue to support and develop BLAST+ to best suit your needs. You can easily opt-out of sending information about your searches if you wish by following the instructions below. This offers you greater privacy control than sending searches over the internet using web tools or the -remote option on a BLAST+ executable, which also accesses the web service. Information sent back to NCBI is limited to the name of the BLAST program, database metadata, a few BLAST parameters, as well as the number and total size of your queries without any data association that might reveal the context of your research. No sequences from your queries or database are sent to the NCBI. An example set of data from a BLAST search is provided below. More information about each item is shown in the table following the list. IP=27.18.28.18comp\_based\_stats=2db\_date=Aug 26, 2020 3:12 AMdb\_length=17965829db\_name=swissprotdb\_num\_seqs=474714evaluator\_threshold=10.000000exit\_status=0hitlist\_size=500mcbi\_app=standalone-blastncbi\_location=be-mdncbi\_role=productionnum\_queries=1num\_threads=2os=UNIXoutput\_fmt=11program=blastqueries\_length=6569ram\_time=3.076507task=blastversion=2.11.0view\_in\_own\_window Reported parameter Description IP The apparent IP address of the machine running BLAST comp\_based\_stats Composition based statistics setting See Command-line options in the manual. db\_date Creation date of the BLAST database db\_length Length (size) of the database in letters (bases or amino acid characters) db\_name BLAST database name db\_num\_seqs Number of sequences in the BLAST database. evaluate\_threshold Expect value limit. See Command-line options exit\_status BLAST program exit status. The value '0' indicates success. See the Exit codes in the manual for more information. hitlist\_size Number of matches to return. This is the same value as the max\_target\_seqs option. See Command-line options in the manual. ncbi\_app Parameter used by NCBI application logging. All BLAST programs return 'standalone-blast' ncbi\_location Default parameter for BLAST. Value always 'be-me' for (Bethesda, Maryland) ncbi\_role Default parameter. Value always 'production'. num\_queries Number of query sequences in the BLAST search. You can opt-out of the usage reporting by adding a .ncbirc (UNIX like) or ncbi.ini (Windows) configuration file. In the configuration file you should add a line under the BLAST section to set BLAST\_USAGE\_REPORT to false. See here for details on setting up a configuration file. You may also opt-out of the usage reporting by setting the environment variable BLAST\_USAGE\_REPORT to false. In bash (under LINUX) this command would be: export BLAST\_USAGE\_REPORT=false Note that this environment variable is only set in the shell (i.e., window) you are currently using and will not be set the next time you login. To permanently opt-out, this variable should be set every time a new shell is opened or with a configuration file, as described above. You can also set this environment variable, turning off usage reporting, when using BLAST+ docker by adding the -e option to your docker invocation: -e BLAST\_USAGE\_REPORT=false The NLM privacy policy is available here. outfmt string 0 alignment view options: 0 = pairwise, 1 = query-anchored showing identities, 2 = query-anchored no identities, 3 = flat query-anchored, show identities, 4 = flat query-anchored, no identities, 5 = XML Blast output, 6 = tabular, 7 = tabular with comment lines, 8 = Text ASN.1, 9 = Binary ASN.1, 10 = Comma-separated values, 11 = BLAST archive format (ASN.1) 12 = Seqalign (JSON), 13 = Multiple-file BLAST JSON, 14 = Multiple-file BLAST XML, 15 = Single-file BLAST JSON, 16 = Single-file BLAST XML, 17 = Sequence Alignment/Map (SAM), 18 = Organism Report/Options 6, 7, and 10 can be additionally configured to produce a custom format specified by space delimited format specifiers. The supported format specifiers are: qseqid means Query Seq-id, ggi means Query GI, qacc means Query accession, sseqid means Subject Seq-id, sallseqid means All subject Seq-id(s), separated by a ','; sgi means Subject GI, sallgi means All subject GIs, sacc means Subject accession, sallacc means All subject accessions, qstart means Start of alignment in query, qend means End of alignment in query, sstart means Start of alignment in subject, send means End of alignment in subject, qseq means Aligned part of query sequence, sseq means Aligned part of subject sequence, eval means Expect value, bitscore means Bit score, score means Raw score, length means Alignment length, pident means Percentage of identical matches, nident means Number of identical matches, mismatch means Number of mismatches, positive means Number of positive-scoring matches, gapopen means Number of gap openings, gaps means Total number of gap openings, gap ppos means Percentage of positive-scoring matches, frames means Query and subject frames separated by a '/'; rframe means Query frame, sframe means Subject frame, btop means Blast traceback operations (BTOP), staxids means unique Subject Taxonomy ID(s), separated by a ','; (in numerical order) scinames means unique Subject Scientific Name(s), separated by a ','; sctaxnames means unique Subject Taxonomy Name(s), separated by a ','; (in alphabetical order) skingdoms means unique Subject Super Kingdom(s), separated by a ','; (in alphabetical order) stitle means Subject Title, salltitles means All Subject Title(s), separated by a ','; sstrand means Subject Strand, qcovs means Query Coverage Per Subject (for all HSPs), qcovhsp means Query Coverage Per HSP, qcovs is a measure of Query Coverage that counts a position in a subject sequence only once. The second time the position is aligned to the query is not counted towards this measure. When not provided, the default value is: 'qseqid sseqid pident length mismatch gapopen qstart qend sstart send eval bitscore', which is equivalent to the keyword 'std'. Created: June 23, 2008; Last Update: January 7, 2021. Estimated reading time: 2 minutes. A BLAST search against a database requires at least a -query and -db option. The command: blastn -db nt -query nt.fsa -out results.out will run a search of nt.fsa (a nucleotide sequence in FASTA format) against the nt database, printing results to the file results.out. If "-out results.out" had been left off, the results would have been printed to stdout (i.e., the screen). The blastn application searches a nucleotide query against a nucleotide database. To send the search to our servers and databases, and the -remote option: blastn -db nt -query nt.fsa -out results.out -remote See more about this option in the section below. BLAST+ remote service. The BLAST+ applications print documentation when invoked with the -h or -help option. The -h option provides abbreviated help, and the -help flag provides more extensive documentation. For example, use -help to get a list of output options for the -outfmt option. Create a custom database from a multi-FASTA file of sequences with this minimal command: makeblastdb -in mydb.fsa -dbtype nucl -parse\_seqs See the section below. Building a BLAST database with local sequences, for more details. The BLAST databases are required to run BLAST locally and to support automatic resolution of sequence identifiers. Documentation about these identifiers can be found at: The databases may be retrieved automatically with the update\_blastdb.pl PERL script, which is included as part of this distribution. This script will download multiple tar files for each BLAST database volume if necessary, without having to designate each volume. For example: update\_blastdb.pl --decompress swissprot will download all the relevant swissprot tar files. The script can also compare your local copy of the database tar file(s) and only download tar files if the date stamp has changed reflecting a newer version of the database. This will allow the script run on a schedule and only download tar files when needed. Documentation for the update\_blastdb.pl script can be obtained by running the script without any arguments (perl is required). RPS-BLAST ready databases are available at ftp://ftp.ncbi.nlm.nih.gov/pub/mmdb/cdd/The BLAST taxonomy database is required in order to print the scientific name, common name, blast name, or super kingdom as part of the BLAST report or in a report with blastdbcmd. The BLAST database contains only the taxid (an integer) for each entry, and the taxonomy database allow BLAST to retrieve the scientific name etc. from a taxid. The BLAST taxonomy database consists of a pair of files (taxdb.txt and taxdb.btd) that are available as a compressed archive from the NCBI BLAST FTP site (ftp://ftp.ncbi.nlm.nih.gov/blast/db/taxdb.tar.gz). The update\_blastdb.pl script can be used to download and update this archive; it is recommended that the uncompressed contents of the archive be installed in the same directory where the BLAST databases reside. Assuming proper file permissions and that the BLASTDB environment variable contains the path to the installation directory of the BLAST databases, the following commands accomplish that: # Download the taxdb archive perl update\_blastdb.pl taxdb# Install it in the BLASTDB directory gunzip -cd taxdb.tar.gz | (cd \$BLASTDB; tar xvf -) While the previous chapters covered installing and using a few bioinformatics tools as examples of the process, there is one nearly ubiquitous tool: BLAST, or Basic Local Alignment Search Tool. Given one or more query sequences (usually in FASTA format), BLAST looks for matching sequence regions between a subject and a query set. A sufficiently close match between subsequences (denoted by arrows in the figure above, though matches are usually longer than illustrated here) is called a high-scoring pair (HSP), while a query sequence is said to hit a target sequence if they share one or more HSPs. Sometimes, however, the term "hit" is used loosely, without differentiating between the two. Each HSP is associated with a "bitscore" that is based on the similarity of the subsequences as determined by a particular set of rules. Because in larger subject sets some good matches are likely to be found by chance, each HSP is also associated with an "E value," representing the expected number of matches one might find by chance in a subject set of that size with that score or better. For example, an E value of 0.05 means that we can expect a match by chance in 1 in 20 similar searches, whereas an E value of 2.0 means we can expect 2 matches by chance for each similar search. BLAST is not a single tool, but rather a suite of tools (and the suite grows over the years as more features and related tools are added). The most modern version of the software, called BLAST+, is maintained by the National Center for Biotechnology Information (NCBI) and may be downloaded in binary and source forms at ftp://ftp.ncbi.nlm.nih.gov/blast/executables/blast+/LATEST/. This chapter only briefly covers running BLAST on the command line in simple ways. Reading the help information (e.g., with blastn -help) and the NCBI BLAST Command Line Applications User Manual at is highly recommended. The NCBI manual covers quite a few powerful and handy features of BLAST on the command line that this book does not. BLAST Types The programs in the BLAST+ suite can search for and against sequences in protein format (as we did for the HMMER example) and in nucleotide format (A's, C's, T's, and G's). Depending on what type the query and subject sets are, different BLAST programs are used. While two nucleotide sequences (N comparisons in the figure above) may be compared directly (as may two protein sequences, represented by P), when we wish to compare a nucleotide sequence to a protein sequence, we need to consider which reading frame of the nucleotide sequence corresponds to a protein. The blastx and tblastn programs do this by converting nucleotide sequences into protein sequences in all six reading frames (three on the forward DNA strand and three on the reverse) and comparing against all of them. Generally such programs result in six times as much work to be done. The tblastx program compares nucleotide queries against nucleotide subjects, but it does so in protein space with all six conversions compared to all six on both sides. Other more exotic BLAST tools include psblast, which produces an initial search and tweaks the scoring rules on the basis of the results; these tweaked scoring rules are used in a second search, generally finding even more matches. This process is repeated as many times as the user wishes, with more dissimilar matches being revealed in later iterations. The deltablast program considers a precomputed database of scoring rules for different types of commonly found (conserved) sequences. Finally, rpblast searches for sequence matches against sets of profiles, each representing a collection of sequences (as in HMMER, though not based on hidden Markov models). All this talk of scoring rules indicates that the specific scoring rules are important, especially when comparing two protein sequences. When comparing protein sequences from two similar species, for example, we might wish to give a poor score to the relatively unlikely match of a nonpolar valine (V) to a polar tyrosine (Y). But for dissimilar species separated by vast evolutionary time, such a mismatch might not be as bad relative to other possibilities. Scoring matrices representing these rule sets with names like BLOSUM and PAM have been developed using a variety of methods to capture these considerations. A discussion of these details can be found in other publications. Each of the various programs in the BLAST suite accepts a large number of options; try running blastn -help to see them for the blastn program. Here is a summary of a few parameters that are most commonly used for blastn et al.: -query The name (or path) of the FASTA-formatted file to search for as query sequences. -subject The name (or path) of the FASTA-formatted file to search in as subject sequences. -evaluate Only HSPs with E values smaller than this should be reported. For example: -evaluate 0.001 or -evaluate 1e-6. -outfmt How to format the output. The default, 0, provides a human-readable (but not programmatically parseable) text file. The values 6 and 7 produce tab-separated rows and columns in a text file, with 7 providing explanatory comment lines. Similarly, a value of 10 produces comma-separated output; 11 produces a format that can later be quickly turned into any other with another program called blast\_formatter. Options 6, 7, and 10 can be highly configured in terms of what columns are shown. -max\_target\_seqs When the output format is 6, 7, or 10 for each query sequence, only report HSPs for the first different subject sequences. -max\_hsps For each query/target pair, only report the best HSPs. -out Write the output to as opposed to the default of standard output. BLAST Databases No doubt readers familiar with BLAST+ have been curious: aren't there databases of some kind involved in BLAST searches? Not necessarily. As we've seen, simple FASTA files will suffice for both the query and subject set. It turns out, however, that from a computational perspective, simple FASTA files are not easily searched. This BLAST+ update tool called makeblastdb that converts a subject FASTA file into an indexed and quickly searchable (but not human-readable) version of the same information, stored in a set of similarly named files (often at least three ending in .pin, .psg, and .pnr for protein sequences, and .nln, .nsg, and .nhr for nucleotide sequences). This set of files represents the "database," and the database name is the shared file name prefix of these files. Running makeblastdb on a FASTA file is fairly simple: makeblastdb -in -dbtype nucl -parse\_seqs, where is one of prot or nucl, and is a human-readable title (enclosed in quotes if necessary). The .nhr seqs flag indicates that the sequence IDs from the FASTA should be included in the database so that they can be used in outputs as well as by other tools like blastdbcmd (discussed below). Once a BLAST database has been created, other options can be used with blastn et al.: -db The name of the database to search against (as opposed to using -subject). -num\_threads Use CPU cores on a multicore system, if they are available. When using the -db option, the BLAST tools will search for the database files in three locations: (1) the present working directory, (2) your home directory, and (3) the paths specified in the \$BLASTDB environment variable. The tool blastdbcmd can be used to get information about BLAST databases—for example, with blastdbcmd -db -info—and can show the databases in a given path with blastdbcmd -list (so, blastdbcmd -list \$BLASTDB will show the databases found in the default search paths). This tool can also be used to extract sequences or information about them from databases based on information like the IDs reported in output files. As always, reading the help and documentation for software like BLAST is highly recommended. Running a Self-BLAST To put these various tools and options to use, let's consider using blastp to look for proteins that are similar in sequence to other proteins in the yeast exome. First, we'll need to use wget to download the default of standard output. BLAST Databases No doubt readers familiar with BLAST+ have been curious: aren't there databases of some kind involved in BLAST searches? Not necessarily. BLAST Databases No doubt readers familiar with BLAST+ have been curious: aren't there databases of some kind involved in BLAST searches? Not necessarily. As we've seen, simple FASTA files will suffice for both the query and subject set. It turns out, however, that from a computational perspective, simple FASTA files are not easily searched. This BLAST+ update tool called makeblastdb that converts a subject FASTA file into an indexed and quickly searchable (but not human-readable) version of the same information, stored in a set of similarly named files (often at least three ending in .pin, .psg, and .pnr for protein sequences, and .nln, .nsg, and .nhr for nucleotide sequences). This set of files represents the "database," and the database name is the shared file name prefix of these files. Running makeblastdb on a FASTA file is fairly simple: makeblastdb -in -dbtype nucl -parse\_seqs, where is one of prot or nucl, and is a human-readable title (enclosed in quotes if necessary). The .nhr seqs flag indicates that the sequence IDs from the FASTA should be included in the database so that they can be used in outputs as well as by other tools like blastdbcmd (discussed below). Once a BLAST database has been created, other options can be used with blastn et al.: -db The name of the database to search against (as opposed to using -subject). -num\_threads Use CPU cores on a multicore system, if they are available. When using the -db option, the BLAST tools will search for the database files in three locations: (1) the present working directory, (2) your home directory, and (3) the paths specified in the \$BLASTDB environment variable. The tool blastdbcmd can be used to get information about BLAST databases—for example, with blastdbcmd -db -info—and can show the databases in a given path with blastdbcmd -list (so, blastdbcmd -list \$BLASTDB will show the databases found in the default search paths). This tool can also be used to extract sequences or information about them from databases based on information like the IDs reported in output files. As always, reading the help and documentation for software like BLAST is highly recommended. Running a Self-BLAST To put these various tools and options to use, let's consider using blastp to look for proteins that are similar in sequence to other proteins in the yeast exome. First, we'll need to use wget to download the default of standard output. BLAST Databases No doubt readers familiar with BLAST+ have been curious: aren't there databases of some kind involved in BLAST searches? Not necessarily.
